

Hao Deng, Charles Haiwen

For our AI approach, we took a more simplistic approach by having the AI patrol around the map until they spotted the player (player was in vision uncrouched for too long) and then would have it follow the player's last known location (updated by vision) until the position was no longer accurate, then had it return to its original route.

Hao:

For this assignment, I primarily focused on building the gameplay systems of the game. I worked on the player controls, the game logic, the agent navigation, AI, and detection. Overall it was a pretty tough assignment as there were a lot of things to do in the game, but I found it quite interesting. I ported over my camera controls from assignment 3 and found they worked pretty well for this game, only needing to disable vertical look to compensate for the third person perspective. I also found the state machine pretty interesting to work with and there are many more things we can do with it if we wanted a more complex AI. I think I did a good job on the navigation with a chance to go to a random spot on the map, or patrol the map using a linked list checkpoint system like assignment 1. Overall, it was a pretty enjoyable experience and certainly an interesting one.

Charles:

For this assignment, I primarily focused on building out the level using ProBuilder, then incorporating and baking the NavMesh over the level created using ProBuilder. I was surprised to learn how much support Unity has for quick prototyping by incorporating these two tools, and how much functionality already exists within Unity for them without supplementary programming. Working with ProBuilder was extremely similar to the many hours I've spent working in Blender, albeit with some restrictions, and once I started getting hands-on practice with NavMeshes, it felt pretty intuitive to use, even when incorporating layers and NavMesh modifier components.
